BACKGROUND

This document is an entirely fictional demonstration, not a scientific study.

The example asks whether libraries with longer opening hours also record more visits.

A relationship between opening hours and visits would not establish causation.

METHODS

The fictional dataset contains twelve libraries observed during one illustrative week.

Six libraries are placed in a shorter-hours group and six in a longer-hours group.

The method compares the average number of visits between the two groups.

RESULTS

The shorter-hours group has an illustrative mean of 120 visits per library.

The longer-hours group has an illustrative mean of 180 visits per library.

The difference between the two illustrative group means is 60 visits.

DISCUSSION

Library size and neighborhood population could explain part of the observed difference.

The example does not measure uncertainty or test the effects of changing opening hours.
